Research Proposal - CiCTrie

Or karni & Daniel Solomon

July 15, 2017

1 Introduction

CTrie[1][2] (or concurrent hash-trie) is a concurrent *thread-safe*, *lock-free* implementation of a hash array mapped trie. This data structure is consists of *key-value* pairs and it supports the following operations:

- **insert**: add a new *(key, value)* pair.
- **remove**: remove a *(key, value)* pair if it exists.
- **lookup**: find the *value* (if any) for a specific *key*.

In addition the **CTrie** data structure has a *snapshot* operation which is used to implement consistent *iterators*. In fact **CTrie** is the first known concurrent data structure that supports *O(1)*, *atomic*, *lock-free* snapshots.
The **CTrie** implementation is based on single-word *compare-and-swap* instructions.

2 Goals and Objectives

CTrie requires dynamic memory allocation, up until now, most implementations of this data structure rely on the existence of a garbage collection mechanism in the targeted platforms. The first implementation was in *Scala* by its very own author *Alexander Prokopec*. Since then there were few more implementations for *Java*, *Go* and more.
CiCTrie - *C implementation of* ***CTrie*** aims for the following objects:

- Implement **CTrie** in *C* using *hazard pointers*[3].
- Bench mark our implementation versus the *Java* implementation.

In order to make sure our implementation is lack of memory leaks we will use the *valgrind*[4] framework tool.

3 Previous Work

A quick search on the web will result a few projects that aimed to achieve our first goal, all of them are incomplete or missing memory management:

- **ctries**[5] (c implementation) - **incomplete**.
- **unmanaged-ctrie**[6] (c++ implementation) - **no attempt to manage memory allocation**.
- **concurrent-hamt**[7] (Rust implementation) - The only complete implementation using hazard pointers known.
